

CS101C: Introduction to Programming (Using C)

Autumn 2025

Nikhil Hegde
Achyut Mani Tripathi

Week7: Functions, Sorting

This week

- Application of pointers
 - a. Modular programming (functions)
- Call-by-value, Call-by-reference
- Global variables, static variables
- Sorting

Functions

- You have seen functions `main`, `printf`, `scanf`, `pow` (anybody?)
 - `int main()`
 - `printf("My name is %s",name);`
 - `scanf("%d",&x);`

`Return values`, `function name`, function arguments and parameters

Functions

- Let us define our own function to swap.

```
void swap(int a, int b){  
    int tmp = a;  
    a = b;  
    b=tmp;  
    return;  
}
```

Function parameters, return statement, void type

Functions

- Let us call the function swap from main.

```
int main(){  
    int a=10;  
    int b=20;  
    swap(a, b);  
    printf("a=%d, b=%d",a,b);  
    return 0;  
}
```

Function call / call site.

Functions

```
int main(){  
    int a=10;  
    int b=20;  
    swap(a, b);  
    printf("a=%d b=%d",a,b); // prints a=10, b=20  
}
```

Call-by-value

Functions

- Let us define another version of the function to swap.

```
void swap2(int *a, int *b){  
    int tmp = *a;  
    *a = *b;  
    *b=tmp;  
    return;  
}
```

Function parameters, return statement, void type

Functions

```
int main(){  
    int a=10;  
    int b=20;  
    swap2(&a, &b);  
    printf("a=%d b=%d",a,b); // prints a=20, b=10  
}
```

Call-by-reference

Functions Declaration vs. Function Definition

- `void swap2(int *a, int *b); //declaration`
- `//definition follows`

```
void swap2(int *a, int *b){  
    int tmp = *a;  
    *a = *b;  
    *b=tmp;  
    return;  
}
```

Functions Declaration vs. Function Definition

- Why you need a declaration?

So that you do not have to define the function before the function call site.

- You can define a function after the call site in the same .c file
- You can define a function in another .c file!

Global and Static variables

- Global variables are visible to all functions in the program.
Initialized to zero
- Static variables are visible inside a single function only but retain their previous value when the function is called again

see function.c shared in codeexample directory

Sorting - Selection sort

- Repeatedly find the minimum element in the unsorted array and put it at the beginning.
 - Divides the input array into 2 pieces - sorted and rest.
 - *All elements in sorted are smaller than any element in the rest – invariant*
 - Works by growing sorted and shrinking rest

Selection sort - example

- A cursor dividing sorted and rest

Selection sort - example

Selection sort - example

Selection sort - example

Selection sort - example

-1	0	2	3	4	9
----	---	---	---	---	---

Sorting algorithms - Evaluation

- Many metrics used for evaluating sorting algorithms.
- Two most common metrics are:
 - How many comparisons are involved?
 - How much data movement is involved?

Selection sort - pseudocode

```
1 int input[N] = //input
2 int cursor = 0 //initial position of the cursor
3 for(cursor = 0; cursor < N; cursor++)
4     //sorted list from [0,cursor)
5     //rest of the list from [cursor, N)
6     for(i = cursor; i < N; i++)
7         //search the rest of the list to find the smallest value
8         //swap the smallest value with the value at input[cursor]
```

Selection sort - Analysis

```
1 int input[N] = //input
2 int cursor = 0 //initial position of the cursor
3 for(cursor = 0; cursor < N; cursor++)
4     //sorted list from [0,cursor)
5     //rest of the list from [cursor, N)
6     for(i = cursor; i < N; i++)
7         //search the rest of the list to find the smallest value
8         //swap the smallest value with the value at input[cursor]
```

Selection sort - Analysis

```
1 int input[N] = //input
2 int cursor = 0 //initial position of the cursor
3 for(cursor = 0; cursor < N; cursor++)
4     //sorted list from [0,cursor)
5     //rest of the list from [cursor, N)
6     for(i = cursor; i < N; i++)
7         //search the rest of the list to find the smallest value
8         //swap the smallest value with the value at input[cursor]
```

- inner loop runs N times, (N - cursor) iterations every time.

$$\begin{aligned} &= \sum_{i=0}^{N-1} N - i \\ &= \sum_{i=1}^N i \end{aligned} = \frac{N(N+1)}{2}$$

Selection sort - Analysis

- outer loop runs for N iterations
- inner loop runs for $\sim N(N+1)/2$ iterations
 - inner loop dominates

1. Approximately how many array write operations occur?

2. Double the input, how long does Selection sort take?

Sorting - Insertion sort

- Iterate through the array one element at a time, build a sorted partial list.
 - Divides the input array into 2 pieces - sorted, key.
 - Inserts key into its right place in sorted.
 - Works by growing sorted

Insertion sort - example

- Inserting key at its correct place in the sorted list

- Start from index=1 because a list of 1 item is trivially sorted.
- Is $a[key] < a[key-1]$
 - YES: swap($a[key]$, $a[key-1]$)
 - NO: done with current element. $a[key]$ is the largest seen so far.

Recap: Strings and Variables

Strings

- Array of char
- Terminated by the null character ‘\0’ as per convention
- Example:

```
char s[]="CSE";
```

	'C'	'S'	'E'	'\0'
Address	0x7ffc510	0x7ffc511	0x7ffc512	0x7ffc513
Value	69	67	69	0

Strings - Initializing

- `char s1[3];`
- `s1[0]='H'; //ASCII 72`
- `s1[1]='i'; //ASCII 105`
- `s1[2]='\0'; //ASCII 0`
- `char s2[]="Hi";`
- `char s3[]={ 'H', 'i', '\0' };`
- `char* s4="Hi";`
- `char s5[] = {72, 105, 0};`

String Literals

- String Literals
- Example:
 - `printf("Hello World\n");`
 - `char *s = "Hi";`
- On data segment (initialized)
 - Cannot modify them

Exercise – Identifying memory segments (strings)

```
void oat(char pie)
{
    char ham;
    char bun[4];
    char* ice = "pop";
    static char egg = 1;
    static char nut;
}

char jam = 2;
char tea;
```

The diagram identifies the memory segments for the following code elements:

- `pie` (parameter) → parameter
- `ham` (local variable) → Local variable
- `bun` (statically allocated array) → Statically allocated array / local variable
- `"pop"` (string literal) → String literal
- `ice` (address of a string literal) → Address (still a local variable)
- `egg` (static variable) → Static variable
- `nut` (static variable) → Static variable
- `jam` (global variable) → Global variable
- `tea` (global variable) → Global variable

- Print the length of a string using `strlen`

```
#include<string.h>
```

```
char s[]="Hello";  
printf("%d\n",strlen(s));
```

- Use format specifier `%s` to print string values

```
printf("%s\n",s);
```
